

Status and claim ledger

Repository source: `certificate/terminal_handoff_v11/STATUS.md`

ESTABLISHED INSIDE THIS AUDIT

- The existing terminal row generator was reproduced exactly against the archived `v1.0.0` `03B02` arrays and coefficient.
- The new rows `03B02A` and `03B02B` are exact rational certificates on a gap-free split of the original `03B02` interval.
- Every unchanged lower-branch row clears the proposed theorem coefficient.
- The unchanged exact near-Jung rational lower clears the proposed theorem coefficient.
- The proposed coefficient strictly exceeds the public `v1.0.0` coefficient.
- Two terminal subintervals are sufficient; 3-way, 4-way, and doubled-grid variants do not improve the universal minimum at the fixed handoff.
- All tested admissible left shifts of `R_*` lower the near-Jung branch.

PROPOSED / NOT YET PROMOTED

$$\text{Vol}(K) \geq \frac{26221074253\pi}{200000000000}d^3 = 0.4118796712122863775\dots d^3.$$

This is a repository-integration candidate for `v1.1.0`.

NUMERICAL AUDIT

- Python binary64 audit: PASS.
- Matching base-R audit: prepared, not run in the construction environment.

NOT ESTABLISHED BY THIS PACKAGE

- Public `v1.1.0` release status.
- A stronger theorem than the stated candidate coefficient.
- Equality, sharpness, a minimizing body, or Meissner extremality.
- Any benefit from redesigning the near-Jung fan or changing theorem architecture.
