Record date: September 19, 2026 **Package version:** 0.1.0-dev **Public remote:** not yet created

This document records reproducibility tests performed while constructing the fresh-history public package. A final tagged-checkout test will be added before release.

Results at a glance

Checkpoint	Source form	Result
Standalone certificate root	Git bundle at commit 21 a175010fb18d74e11286ef0e1135cb32c47053	Exact Python, binary64, ten tests, base R, checksums, and clean status passed
Adversarial mutation overlay	Clean clone of the standalone bundle plus overlay	Seven corruptions rejected; full Python path and checksums passed
Lean Paper v1 overlay	Clean clone of the preceding content plus overlay	Paper reconciliation, manuscript build, Markdown pairs, checksums, and construction-environment PDF preflight passed
Complete release-document overlay	Clean clone of the preceding content plus this checkpoint	Exact/reconciliation/document checks and fresh-extraction PDF build/preflight passed during packaging

The later overlay checkpoints were constructed before their user-side commit hashes were available to this document. They are identified by content and archive checksums in the corresponding transfer records rather than by invented Git identifiers.

1. Standalone certificate bundle

The first fresh-history commit was

21a175010fb18d74e11286ef0e1135cb32c47053
Add standalone exact universal certificate

The named author verified the supplied ZIP checksum, initialized an empty `main` repository, checked both SHA-256 manifests, installed NumPy 2.3.5 in a Python 3.14 virtual environment, and ran the exact verifier, independent binary64 audit, and ten tests. The independent base-R audit also ended with its required pass marker.

After the transcript and manifests were refreshed, all checksums passed and `git status --short` was empty before and after the root commit.

2. Mutation checkpoint

A clean clone of the bundle was used to apply the adversarial-test overlay. The complete Python path passed and seven deliberately corrupted objects were all rejected. Root and certificate checksum manifests passed before and after the run. A second clean extraction of the final overlay reproduced the same result.

The theorem coefficient and authoritative certificate JSON did not change.

3. Paper checkpoint

The lean Paper v1 overlay was applied to the post-mutation tree. The following passed in the construction environment:

- exact and binary64 certificate paths;
- ten reconstruction tests;
- seven mutation tests;
- paper/certificate reconciliation;
- clean LaTeX build;
- Markdown/PDF source pairing;
- Poppler page/font/text preflight;
- page-by-page visual inspection of the nine-page manuscript;
- all nested checksum manifests.

On the named author's Mac, the manuscript and Markdown builds and pair checks passed. Poppler was not installed locally, so `pdfinfo`, `pdffonts`, and `pdftotext` preflight was correctly deferred to the hosted Ubuntu document job. No repository change was needed for that local dependency difference.

The named author reported the Paper v1 commit complete with a clean working tree at 1:41 PM Eastern time on September 19, 2026. The exact commit hash will be recorded after the next repository bundle or before release.

4. Release-document checkpoint

The release-document checkpoint adds the reproducibility, trust-boundary, claims, audit, source-ledger, exact-constants, proof-ledger, release-note, and release-checklist materials. During construction it was applied to a clean reconstruction of the committed content and tested as a fresh extraction.

The packaging audit requires:

- current root, certificate, paper, and rendered-document manifests;
- exact certificate and mutation suites;
- exact-constants generation check;
- release-document presence, claim-boundary, and relative-link checks;
- paper/certificate reconciliation;
- one PDF for every Markdown source;
- valid embedded-font and extractable-text preflight in the construction environment;
- clean staged-diff checks.

The exact results and archive hash are reported with the overlay transfer. The named author's local base-R replay remains required after applying the overlay, because R is unavailable in the construction container.

Environment notes

Construction environment

Linux x86_64 Python 3.13.5

```
NumPy 2.3.5
Rscript unavailable
Pandoc, XeLaTeX, latexmk, and Poppler available
```

Named-author Mac replay

```
macOS
Python 3.14
NumPy 2.3.5
base R available
Poppler command-line tools not installed
```

The exact R version was not captured in the archived local transcript and is therefore not inferred. The hosted workflow declares R 4.6.1.

Interpretation

These checks show that the supplied source tree is self-contained, the finite programs replay in multiple implementations, the documentation builds, and no private repository is needed. They do not establish independent mathematical review, peer review, novelty, or correctness of every conceptual reduction.

Final release requirement

After public metadata is finalized, the project must repeat the following from a fresh checkout of the exact release tag:

1. checksum verification;
2. full Python and base-R replay;
3. paper and Markdown builds;
4. hosted Poppler preflight;
5. metadata and release-asset verification;
6. final clean working-tree check.

The resulting commit, tag, environments, workflow URLs, and any harmless PDF binary variation should be recorded here rather than silently omitted.
