

Release notes

Repository source: RELEASE_NOTES.md

Unreleased 0.1.0-dev

This is the draft release record for a proposed computer-assisted universal lower bound in the three-dimensional Blaschke–Lebesgue problem. It is not yet a public release or immutable tag.

Proposed result

For every convex body $K \subset \mathbb{R}^3$ of constant width $d > 0$, the package represents the proposed inequality

$$\text{Vol}(K) \geq \frac{26220940089713\pi}{20000000000000} d^3 = 0.4118775637803022742481789259828398710 \dots d^3.$$

The result is universal: no symmetry, smoothness, contact-type, or fixed circumradius assumption appears in the final theorem.

Included in the draft package

- a nine-page LaTeX manuscript and reference PDF;
- one standalone exact-rational certificate;
- immutable JSON, NPZ, TSV, and CSV proof objects;
- an independent NumPy binary64 audit;
- an independent base-R audit;
- ten reconstruction and regression tests;
- seven adversarial proof-object mutation tests;
- automatic paper/certificate and appendix/certificate reconciliation;
- reproducibility, trust-boundary, claims, source, audit, and proof ledgers;
- paired Markdown/PDF documentation;
- SHA-256 manifests for the repository, certificate, paper, and rendered docs;
- a three-job GitHub Actions workflow for Python, R, and PDF/document checks.

Proof architecture

The proof splits the normalized circumradius interval at

$$R_* = \frac{305695601}{500000000} = 0.611391202.$$

The lower branch is a gap-free exact radial certificate whose unique bottleneck is 03B02. In the near-Jung branch, four circumsphere contacts force a 98,306-ray core. An exact determinant transfer, a dominant-edge coordinate-width estimate, and three optimized antipodal cap pairs give

<pre>near-Jung lower = 0.4118796712148324317327979810531508741628745212952960018 handoff margin = 0.0000021074345301574846190550703110031602996750911392740</pre>
--

so the lower-row coefficient is the universal bottleneck.

Verification status

Completed in recorded environments:

- exact finite verification and byte-identical certificate reconstruction;
- independent Python binary64 audit;
- independent base-R audit on the named author’s machine;
- ten regression tests and seven mutation tests;
- paper/certificate and exact-appendix reconciliation;
- manuscript and Markdown/PDF builds;
- construction-environment Poppler preflight and visual PDF inspection;
- clean-source/fresh-extraction checks.

Still required before release:

- final author, affiliation, acknowledgment, license, and citation metadata;
- public repository creation and URL insertion;
- green hosted jobs on the final commit and tag;
- clean tagged-checkout replay;
- immutable release assets and hashes;
- explicit named-author approval of the paper, README, release notes, and announcement.

Scope and limitations

This draft does not prove:

- sharpness or equality;
- rigidity;
- the identity of a minimizing body;
- the Meissner conjecture;
- independent reproduction or peer review.

The Meissner value is an explicit-body comparison value, not a universal minimum established here.

Relationship to prior work

The package builds on classical constant-width geometry, the support-function and spectral perspective developed in recent work, and the direct contact-geometric exact-rational architecture of the public HYRA predecessor. The repository has fresh history and does not alter the earlier public MinVol spectral-bound repository.

A dated source and recent-literature check is recorded in [proof/SOURCE_LEDGER.md](#). It is targeted rather than exhaustive, so this draft avoids an unqualified “best known” claim.

Corrections and versioning

A change to any theorem-bearing proof object, exact verification rule, radius partition, or coefficient requires a new version and explicit mathematical comparison. Corrections must be recorded in release notes; released history must not be silently rewritten.
